RELEASE CANDIDATE / 1.1.0-rc.1

Governed AI Workflow Platform

AI proposes.
Policy authorizes.
Workers execute.

A narrow engineering reference for unavailable-order exceptions: bounded investigation, an independent reviewer and a durable execution boundary.

167	1	2
passing checks, with stated scope	committed sandbox effect in the crash experiment	attempts, one stable receipt

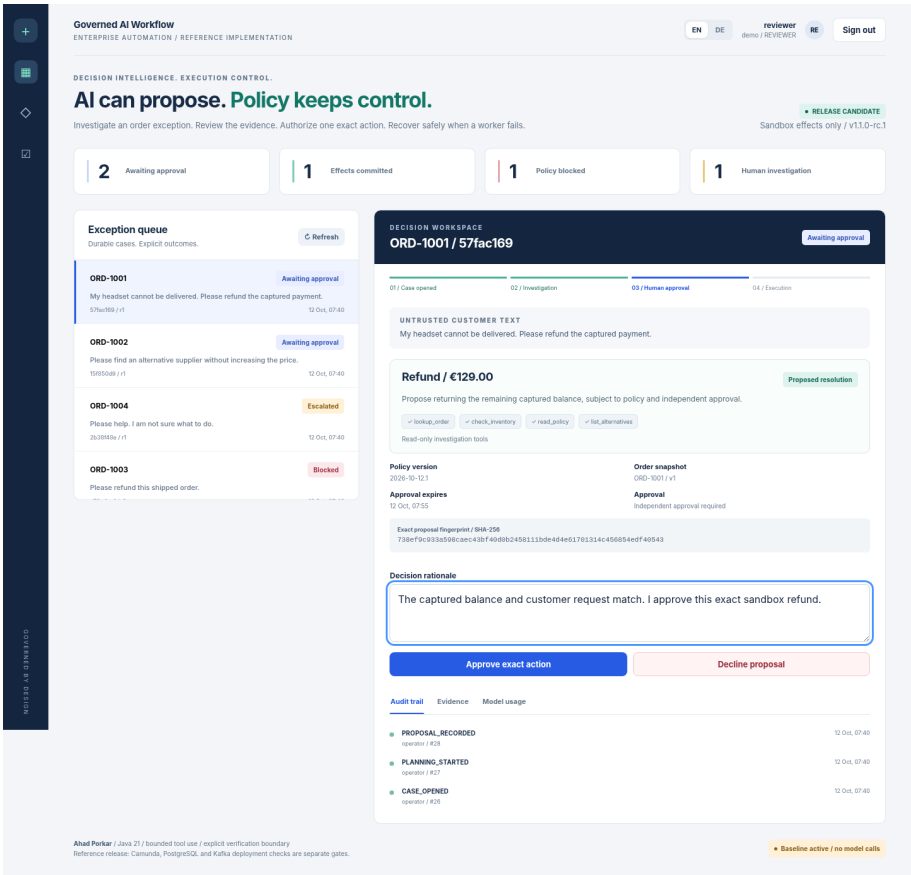

12 October 2026 / Release candidate
English dossier. Full English and German technical guides accompany the source package.

Synthetic business effects. External-stack and live-model acceptance remain open.

01 / REVIEW EXPERIENCE

Review the action. Not just the answer.

The operator experience makes the authority boundary visible: original request, exact proposal, evidence, expiry, independent decision and receipt.

Actual English console with synthetic cases. Rendered in Chromium through the explicitly disclosed DOM harness; this is not native-navigation or CSP acceptance evidence.

Design decision	Why it matters
Visible context	Customer text remains untrusted. Evidence and exact amounts stay beside the decision.
Separate identities	The creator cannot approve their own case. Credentials stay out of browser storage.

02 / AUTHORITY AND ARCHITECTURE

One proposal. Four separate responsibilities.

The model never receives a consequential execution tool. The application owns authorization, state and recovery.

01 **Investigate** > 02 **Validate** > 03 **Review** > 04 **Execute**

Boundary	Implementation
Read tools	Order snapshot, inventory, policy and approved alternatives. Empty arguments prevent selecting another case or tenant.
Policy	Strict proposal schema, integer EUR cents, bounded refunds, admissible cancellation and approved supplier rules.
Approval	Different actor; exact proposal digest; reason and expiry. Tenant, order, versions and request hash are bound.
Commit	Recheck the persisted grant and current facts. Commit ledger update, receipt, audit and outbox atomically.

The file store is a single-writer demonstration. The PostgreSQL adapter intentionally serializes one JSON aggregate. This makes correctness inspectable, not production throughput proven.

REFUND / CANCEL / SWITCH_SUPPLIER / ESCALATE

The first three need independent approval. Escalation has no business-effect arguments.

03 / VERIFICATION

Proof at the failure boundary.

A real worker halts after commit and before acknowledgement. The server restarts. A fresh worker retries and receives the existing receipt.

106
Java contracts

29
HTTP / process tests

9
DOM harness checks

23
repository checks

Test area	Evidence
Concurrency	32 concurrent direct executions and 12 concurrent HTTP retries are exercised; the effect remains singular.
Authorization	Tenant and role isolation, self-approval rejection, digest tampering, stale order/policy and expiry.
Persistence	Rollback, writer locks, corrupted-state failure and durable process restart.
Model protocol	Real local HTTP fixtures exercise the Ollama adapter; no live model quality result is claimed.

```
commit -> worker halt (73) -> server restart
retry -> same receipt -> acknowledge
1 effect / 2 attempts / refundedCents = 12900
```

All 167 selected checks passed. Nine browser checks use an explicit harness because native navigation was blocked. Maven, Spring, real PostgreSQL/Kafka/Camunda and native browser acceptance were not run here. No line/branch coverage percentage is claimed.

04 / BASELINE EVALUATION

Publish the baseline. Publish its weaknesses.

48 manually labelled English/German cases. Exact proposal match checks action, amount and supplier; acceptable disposition checks the resulting state. Neither is business-task completion.

68.75%
exact proposals
33 / 48

83.33%
acceptable dispositions
40 / 48

Failure category	What it teaches
Partial amounts	A request for EUR 25 may receive a proposal for the remaining captured balance. Financial admissibility does not prove customer intent.
Quoted or restricted intent	Action words in quotations, nuanced negation and specific supplier restrictions expose keyword limitations.
Policy rejection	A blocked inadmissible proposal can have an acceptable disposition while failing exact proposal match.

Zero live-model calls and zero executed effects in this evaluation. The Ollama adapter is implemented and protocol-tested; a held-out real-model comparison remains a release gate. Timing values in the JSON are observations from a single synthetic run, not SLOs.

Reproduce the evaluation

```
python scripts/evaluate.py
python scripts/evaluate.py --provider ollama --model MODEL
```

05 / RUN AND INTEGRATE

Run it locally.
Integrate it deliberately.

The independent baseline package needs a Java 21 JDK and Python 3.10+. No Maven, Docker, cloud account or model key is needed for that path.

```
python scripts/run_demo.py
python scripts/worker.py --once
python scripts/test.py --repository
```

Open http://127.0.0.1:8095. Use the generated operator token, then the separate reviewer token from .local/access.json. Approve a synthetic case and run the worker in another terminal. Never publish credentials.

The attachment is not silently overwritten.

The supplied archive is RechnungFlow, not the requested BPMN repository. It remains unchanged. The delivery is an independent module and additive overlay, not a cloned/merged host checkout. The installer defaults to dry-run and refuses wrong projects, symlinks, overwrite conflicts and V100 migration collisions.

```
python scripts/apply_overlay.py TARGET --report dry-run.json
python scripts/apply_overlay.py TARGET --apply
```

The original order tables, payment integrations, APIs and out-of-stock branch are unchanged. A future integration must obtain verified payment/inventory facts and use idempotent, reconciled real connectors.

Host: Java 21 / Spring Boot 3.5.16 / Camunda 8.8.40 / PostgreSQL / Kafka. Observed public baseline, not an executed integration result.

06 / RELEASE GATES

A release candidate. A credible engineering story.

The portfolio value is not unchecked autonomy. It is a system whose permissions, evidence, failure behavior and trade-offs can be inspected.

Gate	Evidence needed
Host integration	Record a clean host commit; apply/review the overlay; pass Maven and PostgreSQL concurrency/rollback tests.
Orchestration	Deploy BPMN; prove Kafka/Camunda progression, duplicate delivery and real worker-failure recovery.
User experience	Run native-browser, keyboard/accessibility and required operating-system checks.
Model quality	Evaluate an actual model on held-out cases; publish failures, latency and cost assumptions.
Production boundary	Replace demo identity, secure all host APIs, review privacy/licenses, test backup/restore and implement real connectors only deliberately.

Primary references and full evidence

[1] Intended host repository and observed baseline.
[2] Ollama native tool-calling protocol.
[3] Camunda runtime licensing.
Inspected 12 October 2026. Local evidence: evidence/verification.json and the named test/evaluation reports. Full technical documentation: docs/en/ and docs/de/.

Application source is MIT; runtime and model rights are separate. No production certification, external publication or employer/customer outcome is implied.
